With that was done. We had our port scanner running on the laptop connected to the WiFi router. It was scanning that, we also connected to the wireless and saw the potential for more hosts. The score after 10 min of scanning was 22 hosts. Almost 35% of the list were on the same internal network, and those were the easy ones. There was no collateral damage for the hosts that were listed. We had two teams in the house, one was a security researcher, and the other was a hacker. We had two laptops connected, one connected to WiFi and the other connected to LAN, and they were ready for the students, we had pre-agreed upon the POC and how to interact with the APs. There are different challenges, and different ways to achieve the goal, and which way works well for your environment. Some of the attacks and the corresponding payload are listed here: Client side attacks: NAT punching: The attacker sends the requests to an internal IP address, and then re-directs the requests to an internal site, and if this happens, there is a special behavior, as this is how the APs are used. Forcing the victim to a site: Forcing the victim to a site: Seeing the network connections (OSI layers): From the diagram above, you see the network connections, and the method used. You also see the attack vector used. Stealing credentials from the victim: Stealing credentials from the victim: Stealing cookies from the victim: Stealing cookies from the victim: Stealing the data: Worm attacks: Botnet DDoS (Distributed Denial Of Service): Botnet
